Introduction

The spider fauna of Turkey is rather poorly known compared to other countries of the world. Up to now, 44032 species of 3905 genera of spiders have been described in the world (Platnick 2013). There are only 979 species, belonging to 53 families known from Turkey (Topçu et al. 2005, Bayram et al. 2013). In this study, we report four spider species as new records for the Turkish spider fauna. For each species, the collected material, localities (with GPS co-ordinates) and data of general distribution are given.

Material and Methods

The spiders were collected from Melendiz Mountains (Niğde Province) of Turkey by using pitfall traps and manual gathering. The specimens were preserved in 70% ethanol. The identification was made by means of a SZX61 Olympus stereomicroscope. The keys of Heimer, Nentwig (1991), Roberts (1995), and Locket, Millidge (1951, 1953) were used for the species identification. The examined specimens are deposited in the Arachnology Museum of Niğde University (NUAM). The general distribution of all species follows Platnick (2013).
